Abstract

We assemble a dataset on technology adoption in 1000 B.C., 0 A.D., and 1500 A.D. for the predecessors to today's nation states. We find that this very old history of technology adoption is surprisingly significant for today's national development outcomes. Our strong and robust results are for 1500 A.D. determining per capita income today. We find technological persistence across long epochs: from 1000 BC to 0 AD, from 0 AD to 1500 AD, and from 1500 AD to the present. Although the data allow only some suggestive tests of rival hypotheses to explain long-run technological persistence, we find the evidence to be most consistent with a model of endogenous technology adoption where the cost of adopting new technologies declines sufficiently with the current level of adoption. The evidence is less consistent with a dominant role for population as predicted by the semi-endogenous growth models or for country-level factors like culture, genes or institutions.

Keywords: Technology adoption, technology history, economic development.

JEL codes: O3, N7.

1. Motivation

Cross-country differences in per capita income in the pre-industrial world were significantly smaller than today. For example, according to Madison (2000), per capita income in the UK in 1500 AD was sixty-eight percent higher than in Mexico. In 2000, it was almost three times larger.

This observation has motivated two conclusions. First, that pre-industrial country conditions, and in particular, the technology adoption level, did not vary much across countries.¹ Second, that pre-industrial country conditions are almost irrelevant to understand current development dynamics. A consequence of these conclusions is the emphasis of economic development practitioners and students on modern determinants of per capita income like quality of institutions to support free markets, economic policies chosen by governments, human capital components such as education and health, or political factors like violence and instability.

Could this discussion be missing an important, much more long-run dimension to economic development? To the extent that history is discussed at all in economic development, it is usually either the divergence associated with the industrial revolution (e.g. Lucas, 2000) or the effects of the colonial regimes.² Is it possible that precolonial, preindustrial history also matters significantly for today's national economic development?

This paper explores these questions both empirically and theoretically. To this end, we assemble a new dataset on the history of technology over 2500 years of history prior to the era of colonization and extensive European contacts. The first significant finding is that there were important technological differences between the predecessors to today's modern nations as long ago as 1000 BC, and that these differences persisted to 0 AD and to 1500 AD (which will be the three data points in our dataset). Further, these precolonial, preindustrial differences have striking predictive power for the pattern of both per capita incomes and technology adoption across nations that we observe today. Our strongest results are for the detailed technology dataset we assemble for 1500 AD, which is an excellent predictor of per capita income today. We find that the results for 1500 AD largely continue to hold when we include continent dummies and geographic controls.

Two questions naturally follow up our findings. First, what mechanisms propagate historical shocks that affect the history of technology adoption into the present? Second, what do our findings teach us about existing growth models? To answer these question, we present a simple model where the stock of technologies adopted reduces the cost of adopting new technologies. Depending on the strength of this elasticity, historical technology adoption will or will not have a significant effect on the adoption of technologies that have come along since the industrial revolution and hence on current development. Hence, our empirical exploration provides an estimate for this elasticity.

¹ This conclusion is not necessarily true as follows from the work of Kremer (1993), Galor and Weil (2000) and Jones (2001, 2005) and Hansen and Prescott (2002). All these papers have Malthusian models where fertility increases with technology. In this context, countries may have significant differences in technology but very small differences in per capita income.

² A notable, honorable, and famous exception is Jared Diamond (1997) .

Our simple model also helps us think about alternative hypothesis that may generate the observed importance of historical technology adoption on current development and, more importantly, it guides us in how to identify them in the data.

One such explanation is related to ideas increasing with population because there are more potential thinkers to create these (non-rival) ideas. More ideas in turn creates better technology which can sustain a larger population, and then the virtuous circle continues. This idea dates back to Simon Kuznets, and Julian Simon and has been formulated more recently by Kremer (1993), Galor and Weil (2000) and by the semi-endogenous models of Jones (1995, 1999, 2001, 2005), Kortum (1997), and Segerstrom (1998). A reduced form of these population and ideas models in technology alone would also show technological persistence, intermediated by population, and so our findings could provide another piece of evidence in support of these models.

However, we think it is interesting to identify whether the persistence of technology also results from a direct propagation mechanism of old to new technology, as opposed to being fully accounted for by the population channel. So we control for population in our regressions. We find that both the persistence of technologies and the effect of historical technology adoption on current development persist after controlling for historical population and for both historical and current population. Hence, our first exploration of the data suggests a direct effect of past technology on future technology that is not fully explained by the population channel.

Other potential propagation mechanisms currently discussed in the literature are institutions, culture or the genetic endowment.³ To identify whether technology or these other factors are propagating historical shocks into the present, we exploit the cross-sector variation in technology adoption and explore whether the persistence of technology adoption holds after including country-year effects and country-sector fixed effects. We find not only that the persistence of technology holds also within sectors but that the magnitude of this effect is comparable to the estimated persistence before including country effects. Further, the persistence within sectors is not driven by any specific sector. In our view, these findings are suggestive that there is a direct technology effect even if institutions, genes or culture also matter since, if these latter factors accounted for all the persistence, they would do so through a common effect on technology adoption across all sectors. This is hard to reconcile with our finding that the magnitude of the effect of historical technology is virtually unchanged after including the country effects. It is plausible that the knowledge from previous adoption experience has an important sector-specificity which would rationalize the within sector persistence in adoption.

³ Spolaore and Wacziarg (2006) have a fascinating exploration of the effect of genetic distance on log-income distance. They take genetic distance as a difference between all characteristics vertically transmitted from parents to children (not only genetic, but even more importantly cultural), and suggest that differences in these characteristics act as a barrier to technology/development diffusion. They find that countries populated by more genetically distant cultures also have more different per capita incomes. This finding is complementary to ours because genetic distance is very persistent and was determined in a distant past. It differs, however, in at least two respects. First, we explore the effects of technology adoption history on current development. Our left hand side variable has a direct effect on development, while genetic distance surely does not have a direct effect on development. It is a proxy for costs of transferring technology. Second, by exploring a relationship in levels we are able to preserve the transitivity of our measures. This is not the case when looking at distances. Ashraf and Galor (2008) have another interesting genetic story, stressing the differences in genetic diversity across regions of the world as a determinant of comparative economic development, through the beneficial impact of diversity on technological creativity.

In summary, what our findings teach us is that technology is remarkably persistent over the very long run, and that very significant inputs that shape the current cross-country distribution of per capita income were determined a long time ago and were likely to be propagated into the current times by the dynamics of technology adoption.

Our paper is clearly related to the influential book by Jared Diamond (1997) *Guns, Germs, and Steel*. One important thesis in Diamond's book is that current development is tied to ancient technologies. Diamond, however, does not systematically test the effect of ancient technologies on modern incomes or studies the propagation mechanisms as we will do here. Perhaps for that reason, the Diamond work did not change much the tendency of development economics to focus on the modern period or at most the colonial period.

In a similar vein, economic historians have been debating the importance of past technology adoption for the adoption of subsequent technologies, especially what triggered the Industrial Revolution in Europe. Mokyr (1990, p. 169) and Rosenberg and Birdzell (1987) argue that technological experience is a long way from being a sufficient condition for the "European miracle", stressing the earlier technological lead of China. Greene (2000), instead, argues that, in the West, Greco-Roman dynamism was part of a long continuum from the European Iron Age to medieval technological progress and the industrial revolution. Mokyr (1990, p. 164) also notes how many technological advances petered out throughout history without leading to a permanent stream of innovation.

However, while economic historians disagree on an initial technology advantage as a sufficient cause of the industrial revolution, their description of technology history reaches a consensus on many mechanisms that cause past technology to have an effect on future technology. (There is no contradiction here – past technology could matter, and yet not be sufficient to explain why Europe and not China experienced the industrial revolution, which could also depend on other factors such as institutions and values). Specifically, they provide many case studies of technological innovation to document mechanisms that support the assumption of our model that a higher initial technology level lowers the cost of adopting new technologies (or in a few cases, raises the benefits of new technologies).

----- INSERT TBLE 1 HERE -----

In Table 1, we list the surprisingly long list of such mechanisms detailed by economic historians (although some of mechanisms are related to each other), along with many of the illustrative examples historians have given from technology history. The examples are skewed towards the Industrial Revolution and after since that is where historians have focused most of their energies and the historical record is most complete (although many Greek/Roman and medieval examples do appear). It is possible that some of the mechanisms only started to operate at the time of the Industrial Revolution. However, we think it is plausible that the Industrial Revolution was only a speeding up of technology dynamics (which we will discuss below), and that many of these dynamic mechanisms will apply to earlier technological eras. If so, then we have a strong a priori case for the persistence of technology over long periods, which we can test against our long run dataset.

Our empirical methodology is very different from the case histories of the technology history literature; we don't claim it to be superior, only a valuable additional method of testing the hypothesis of technology persistence. Clearly, one important barrier that may have prevented other researchers from implementing this strategy is the lack of a data set. One of our contributions is to assemble a data set to explore more definitely these issues.

The rest of the paper is organized as follows. Section 2 presents the data set. Section 3 uncovers the main findings and shows their robustness. Section 4 presents a simple model that rationalizes the facts and some extensions that yield some additional predictions that allow us to identify several competing hypothesis about the nature of the propagation mechanism. Section 5 concludes.

2. Description of technology data set

The historical datasets presented in this paper measure the cross-country level of technology adoption for over 100 countries in three periods: 1000 B.C., 0 A.D. and the pre-colonial period in 1500 A.D. Each dataset acts as a "snap shot" in time, capturing the levels of technology adoption by country throughout the world.

Technology adoption is measured on the extensive margin by documenting whether a country uses a particular technology, not how intensively it is used. For example, in the dataset for 1000 B.C., we consider two transportation technologies: pack animals and vehicles. A country's level of technology adoption in transportation is then determined by whether vehicles and/or draft animals were used in the country at the time. The technologies that we examine change between the ancient period (1000 B.C. and 0 A.D.) to the early modern period (1500 A.D.) to reflect the evolution of the technology frontier.

Our focus on the extensive margin of technology adoption is motivated by data availability constraints and by its historical relevance. It is much easier to document whether a technology is being used in a country (the extensive margin) rather than measuring the degree of its adoption (the intensive margin).⁴ In addition, the extensive margin has been up to 1875 or so a much more significant margin to explain the cross-country variation in technology adoption (Pulkki and Stoneman, 2006).

The technologies in our data sets are state of the art technologies (at the time) in productive activities (i.e. activities that entered GDP) and for which it has been possible to document its presence or absence for a wide range of countries. Of course, it is a very incomplete list since it does not cover all the significant frontier technologies available at the time. However, the number of technologies covered (12 for 1000 BC and 0 AD and 24 for 1500 AD) is sufficient to make precise inferences about the technological sophistication of economies in the distant past. More fundamentally, the criteria for including technologies in our analysis do not generate any bias in our results because they involve the closeness to the World technology frontier in the distant past which, of course, is very different from the current technology frontier.⁵

⁴ It is well documented that the Chinese were using iron for tools by 0 A.D; what is more difficult to assess is the share of tools constructed from iron at the time.

⁵ An argument in line with the appropriate technology literature is that it is optimal that some technologies are not present in some regions. Diamond (1997) for example, argues that horses were ineffective in the tropics. Given the

A related issue is that some sectors are more densely covered than others (i.e. for 1500 AD we have 8 technologies in military but only 2 in metal working). To avoid overweighting sectors where we have been able to collect data on more technologies, we compute the average adoption rate in each sector and then compute the overall adoption level by averaging the sectoral adoption levels. We have also experimented with alternative aggregation approaches obtaining very similar results.

Since our main objective is to analyze the effects that historic technology adoption has on the current state of economic development, our datasets are partitioned using modern day nation states. We use the maps from the CIA's *The World Factbook* (2006) to put into concordance the borders of present day nations with the cultures and civilizations in 1000 B.C., 0 A.D. and 1500 A.D. For example, the technologies used by the Aztecs and their predecessors during pre-colonial times are coded as the ones used by Mexico in 1500 A.D. In cases where a country had multiple cultures within its borders during a certain time period, we take the culture with the highest level of technology adoption to represent that country. This technique is a direct consequence of our goal of measuring the extensive margin of technology adoption in a country. For example, in 1000 B.C. there were multiple cultures residing within Canada's modern day borders. The Initial Shield Woodland was the most technologically sophisticated of these cultures and we therefore use its level of technology adoption to represent Canada in 1000 B.C.

The use of the most advanced culture within a territory for a country's level of technology could induce a mechanical correlation between technology and country size (as measured either by population or land area). The larger the size, the more cultures are being sampled, which makes the maximum of all cultures higher. For population, this "mechanical" effect is really the Kuznets-Simon effect of population on technology mentioned in the introduction, if the most advanced technologies do indeed disseminate within the borders of what is today measured as a country. We will test for this effect in our empirics. For land area, this also could reflect a real economic phenomenon for the same reasons, but it would induce reverse causality between land area and technology. We will examine some simple tests as to whether this affects our results in the empirical section.

Each dataset is constructed following the methodology used by George Murdock and other ethnologists (Murdock 1967; Carneiro 1970; Tuden and Marshall 1972; Barry and Paxson 1971). Each dataset is coded by a team of researchers surveying multiple sources reducing, in this way, the likelihood of measurement error. Researchers take detailed notes including direct quotations and using, when appropriate, two inference techniques: technological continuity (Basalla 1988) and temporal extrapolation (Murdock & Morrow 1970: 314).

technologies in our sample, we view this argument as very anecdotal. It is quite clear that virtually all of the technologies in the three historical datasets have a (large) positive effect on labor productivity in virtually all countries. A related point is that our empirical exploration does not try to establish the reasons for the failure to adopt a technology. Rather, whether this failure had consequences in the (very) long run. In a sense, if in historical times it was optimal not to adopt a technology, it is even more surprising to find negative effects in the (very) long run.

Technological continuity stresses that innovations are a result of previous antecedents; innovations typically do not spontaneously arise without preexisting technologies.⁶ We use this technique to infer that countries with advanced technologies in a particular sector also had more primitive ones. One example that illustrates this technique comes from the military technologies in 1500 A.D. Large warships with over 180 guns on deck were considered the pinnacle of military technology in 1500 A.D. (Black 1996). It is not unreasonable to assume that a country with heavily armed warships also had access to field artillery and muskets. Therefore, in Portugal and Germany, the presence of large warships was used to infer the use of both muskets and field artillery. Temporal extrapolation assumes that a technology maintains some level of persistence over time. A technology adopted fifty to one hundred years earlier is assumed to still be in use.⁷ In addition, in most of the cases, we are able to document that the technology was present in 1550. An example of this is the coding of transportation technology in 1500 Turkey. We code Turkey as having the magnetic compass in the 1500 A.D. dataset based on evidence that it was in use in the Ottoman Empire by 1450.

The datasets for 1000 B.C. and 0 A.D. are derived from the “Atlas of Cultural Evolution”⁸ (henceforward abbreviated as “ACE”). (Peregrine 2003) while we coded the dataset for 1500 A.D. in its entirety. The ACE itself is based on the Encyclopedia of Prehistory (Peregrine & Ember 2001) whose compilation involved multiple data sources and over 200 researchers. The 1500 A.D. dataset involved several researchers and over 200 sources.

It is important to note that, in a majority of cases, the coding of technology adoption is based on direct evidence of the presence or absence of technologies in the countries. A relevant consideration could arise if we had a civilization covering various modern day countries and we did not have any source of evidence that the code for the civilization applies to all the individual countries. In this event, the standard errors for our regressions would be misleading. To avoid this problem, for 1500 AD, we have searched for documentation that allows us to determine the presence or absence on the countries that correspond to historical empires. For example, for the countries that composed the Ottoman empire in 1500, we have documented the presence or absence in each of the countries.

In a few cases, we have not been able to document directly the absence of some specific technology in a given country ‘X’. In these cases, however, we have direct evidence of the absence of the technology in some neighboring country ‘Y’ that has been proven to dominate technologically country ‘X’ at the time. This allows us to infer the absence of the technology in country ‘X’.

An example of this is in our coding of communications in South America. We have little information about the diffusion of these technologies in 1500 AD in Brazil, Uruguay, Paraguay, and Colombia. Since the Incas were the most advanced civilization in South America during that time, any technologies absent from Inca civilization were assumed to be absent in the countries

⁶ See Basalla (1988:30-57) for a number of case studies documenting technological continuity or technological evolution.

⁷This time frame rules out long run technological regression such as the loss of some Roman achievements in medieval Europe or the Chinese ocean-going voyages to East Africa.

⁸ Peregrine (2003) uses BP (Before Present) as the time variable when coding his datasets. We convert the BP time periods to either B.C. or A.D. Peregrine’s 3000 BP dataset is used for our 1000 B.C. dataset and Peregrine’s 2000 BP dataset is used for our 0 A.D. dataset.

listed above. The Incas relied on Quipus (lengths of string knotted at intervals) for communications and had no written records (Scarre 1988:222; Encyclopedia Britannica 2006). This implies that the Incas did not have books or movable type printing. Using this geographic dominance argument, we infer that Brazil, Uruguay, Paraguay, and Colombia did not have these technologies either.

This geographic dominance argument might, however, have consequences on the computation of the standard errors in our regressions. Despite the few occasions where we have used the geographic dominance argument, we avoid this issue by clustering the errors around the areas of technological influence used to code the data. Further, we have checked that our results are robust to clustering the errors by continents.

Finally, there are two potential concerns in interpreting our data that we want to address directly. The first is that countries that were more advanced at the time were more likely to leave records. The second is that currently rich countries may be more likely to find remains that document the existence of technologies in the past.

We do not believe that either of these concerns has a significant influence on our data set. This conclusion is based on three reasons. First, remember that we use direct evidence of the absence of the technologies to code that the technology was not present in a country. That is, lack of evidence on the presence of the technology is not sufficient to code its absence. Second, modern day archeologists dig wherever they believe they can find remains regardless of the origin of the archeologists. Indeed, most of the main archeological discoveries are in developing countries and have been found by archeologists from developed economies. Finally, as we show in section 4.3, our findings about the persistence of technology adoption hold even when we include country (fixed and/or time varying) effects and exploit the cross-sectoral variation in technology adoption. That takes care of any country-level bias including biases in the reporting or collection of data.

2.1 Technology Datasets for 1000 B.C. and 0 A.D.

The datasets for 1000 B.C. and 0 A.D. measure the level of technology adoption for agriculture, transportation, communications, writing, and military on 113 and 135 countries respectively. The “ACE” does not contain any variable that measures directly the technologies used for military purposes. To assess a country’s level of technology adoption for the military we use the “ACE” dataset to determine which metals were available for each culture. Metallurgy is integral for the development of more advanced weapons (Macksey 1993:216; Scarre 1988; Collis 1997:29). The progression from stone to bronze and finally iron corresponded to a progression of more powerful weapons; stone weapons were replaced by bronze swords and daggers; iron weapons were considerably stronger than their bronze predecessors (Hogg 1968:19-22). The relevant data from the ACE and how it is used can be found in Table 2.

_____ Insert Table 2 here _____

An example of how a country is coded in 1000 B.C. and 0 A.D will best illustrate our methodology.

Korea was inhabited by the Mumun peoples in 1000 B.C. The Mumuns had no tradition of either writing or non-written records. The Mumuns however did rely on agriculture as its primary form of subsistence and used pack animals for transportation. In addition the Mumuns produced metalwork and used bronze for tools but not iron (Rhee 2001). The coding for the Mumun entry in the “ACE” dataset (Peregrine 2003) therefore is:

Writing and Records = 1
Technology Specialization = 3
Land Transportation = 2
Agriculture = 3
Tools = 2

Based on this data, we code Korea in 1000 B.C. as:

Communication: Mnemonic or nonwritten records = 0; True Writing = 0
Industry: Pottery = 1; Metalwork = 1
Transportation: Pack or draft animals = 1; Vehicles = 0
Agriculture: 10% or more, but secondary = 1; Primary = 1
Military: Bronze weapons = 1; Iron weapons = 0

We aggregate the technology adoption measures at the sector level by adding all the individual technology measures in the sector and dividing the sum by the maximum possible adoption level in the sector. In this way, the sectoral adoption index is in the interval [0,1]. The overall adoption level in each country and time period is the average of the adoption level across sectors. Obviously, the overall adoption index also belongs to the interval [0,1].

The adoption levels in the four sectors just reported in Korea in 1000 B.C. are the following:

Communications = 0
Industry = 1
Transportation = 0.5
Agriculture = 1
Military = 0.5

And the overall level of technology adoption for Korea in 1000BC is 0.6.

2.2 Technology Dataset for 1500 A.D.

The technology dataset for 1500 A.D. encompasses 113 countries and evaluates the level of technology adoption across the same five sectors (agriculture, transportation, military, industry, and communications) as the previous datasets. Our technology measures outside Europe are estimated before European colonization. It is important to stress, therefore, that our technology measures in 1500 A.D. do not incorporate the technology transferred by Europeans to the rest of the world after European exploration began around 1500.

Obviously, there are a larger number of sources covering the technology adoption patterns in 1500 A.D. than in 1000 B.C. or 0 A.D. This allows us to collect adoption data for 24 technologies

in the four sectors other than agriculture vs. the 11 technologies covered in the data sets for 1000 B.C. and 0 A.D. As a result, our estimate of the level of technology adoption in 1500 A.D. is likely to be more precise than for the earlier periods. Note that, as before, our measures attach equal weight to each of the five sectors, so our overall average is not biased towards sectors in which more technological information is available. So for example, more information is available on military technologies (8) than industrial technologies (2), but military and industry have equal weights in our overall index. For the same reason, closely related technologies within a sector that might risk “double counting” do not increase the weight of that sector in our overall index. Table 3 presents the various technologies measured in 1500 A.D.^{9,10}

_____ INSERT TABLE 3 HERE _____

2.3 Current Technology

To explore whether historical technology differences have ‘persisted’ until current times, we construct a measure of current technology level based on Comin, Hobijn and Rovito (2006). This measure captures (one minus) the average gap in the intensity of adoption of ten major current technologies with respect to the US. These technologies are electricity (in 1990), internet (in 1996), pcs (in 2002), cell phones (in 2002), telephones (in 1970), cargo and passenger aviation (in 1990), trucks (in 1990), cars (in 1990) and tractors (in 1970) all in per capita terms.

More specifically, for each technology, Comin, Hobijn and Rovito (2006) measure how many years ago did the United States last have the usage of technology ‘x’ that country ‘c’ currently has. We take these estimates, normalize them by the number of years since the invention of the technology to make them comparable across technologies, take the average across technologies and multiply the average lag by minus one and add one to obtain a measure of the average gap in the intensity of adoption with respect to the US whose adoption level is one, by construction.

Note that this measure of current technology adoption differs from the historical measures in that it includes the intensive margin. This is the case because in the last 100 years or so, the extensive margin of technology has diffused very quickly across countries. Therefore, the intensive margin of technology adoption is the relevant margin to explain cross-country differences in technology.

Since richer countries tend to demand more intensively new technologies, our measure of current technology adoption will be correlated with per capita GDP. However, as shown in Comin and Hobijn (2008b), there are many other determinants of technology adoption above and beyond per capita income. Hence, the usefulness of having a direct measure of current technology to assess the persistence of technology.

⁹ In our analysis we have experimented with some alternative aggregation schemes such as collapsing the technologies of ships capable of crossing the various oceans into just one technology without any significant change in our results.

¹⁰ Our sectoral and overall technology adoption measures are very robust to reasonable variations in the definition of new technologies. For example, we have explored the effect of aggregating the technology to cross the various oceans into one unique variable. This results in a adoption measure for transportation with a correlation of 0.988 with respect to ours. Similarly, collapsing heavy naval guns and large ships with +180 guns into a unique technology results in a measure of adoption in military with a correlation of 0.996 with our measure.

It is also worthwhile noting that, the major technologies used to summarize the current state of technology, belong to four of the sectors covered by the historical data sets (i.e. all but military). We shall take advantage of this feature of the data when estimating the persistence of technology within sectors in section 4.3.

3. Data analysis

3.1 Cross-country dispersion in technology

We start the data analysis by presenting in Table 4 some descriptive statistics for the overall technology adoption level in 1000BC, 0 AD, 1500 AD and in the present.

_____ INSERT TABLE 4 HERE _____

The increase in the cross-country average of the overall technology adoption level between 1000 B.C. and 0 indicates the diffusion of the technologies described in the ACE. Recall that the technology adoption data set for 1500 A.D. contains different technologies than the first two periods. Therefore, we should not compare the absolute level in 1500 AD with the previous levels.

Table 4 can help us explore how large was the cross-country dispersion in technology adoption. The binary nature of our measures of historical technology adoption for individual technologies provides two benchmarks to interpret the cross-country dispersion in technology adoption.¹¹ First, the maximum range for the average adoption level across countries is the interval $[0,1]$; 0 for a country that has not adopted any of the technologies and 1 for a country that has adopted all the technologies. Second, the maximum cross-country dispersion in adoption would occur when half of the countries have adopted all the technologies and the other half has adopted none. In this case the standard deviation of the average adoption level across countries would be 0.5.

Similarly, a country that has no units of a given modern technology will have a measure of current adoption (for that technology) of 0, while a country that has the US intensity of adoption will be measured as 1. In a few countries and technologies we observe that the intensity of adoption is higher than in the US and the current technology adoption level is higher than one.

Figures 1a through 1c and Table 5 explore further the cross-country variation in the overall technology adoption level. Table 5 explores the variation across continents in overall technology adoption. Figures 1a through 1c present a world map with the overall technology adoption level in each country and historical period. We use four colors to indicate technology adoption levels between 0 and 0.25, between 0.25 and 0.5, between 0.5 and 0.75 and between 0.75 and 1. Darker colors represent a higher overall technology adoption level. Missing values are represented in white.

_____ INSERT TABLE 5 HERE _____

¹¹ The exceptions to this rule are the measures of technology adoption in agriculture.

In all three historical periods, Europe and Asia present the highest average levels of overall technology adoption, while America and Oceania present the lowest, with Africa in between. In current times, the average adoption level is highest in Europe and Oceania (driven by Australia and New Zealand), followed by America, Asia, and Africa.

_____ INSERT FIGURES 1a-1c HERE _____

A glimpse to the figures suffices to note that there is substantial variance in overall technology adoption both across and within continents. To make observation more precise, we decompose the cross-country variation in overall technology adoption between the variation within continents and the variation between continents. In 1000BC, about 65 percent of the variance in overall technology adoption is due to variation within continents and 35 percent due to variation between continents. These proportions are reversed in 0 A.D. and in 1500 A.D. the share of total variance due to the between continent component rises to 78 percent.

Table 6 provides a more detailed comparison of the evolution of overall technology adoption in the most advanced countries. These countries correspond to four historical civilizations: Western Europe, China, the Indian civilization and the Middle Eastern peoples. Western Europe includes Spain, Portugal, Italy, France, United Kingdom, Germany, Belgium and Netherlands. The Indian civilization includes India, Pakistan and Bangladesh. Finally, the Middle Eastern civilization includes Saudi Arabia, UAE, Yemen, Oman, Iraq, Iran, Turkey, Syria, Lebanon, Jordan, Egypt, Libya, Tunisia, Algeria and Morocco.

_____ INSERT TABLE 6 HERE _____

In 1000 B.C. the Middle Eastern empires and China have an overall technology adoption level of 0.95 and 0.9 respectively, while in India and Western Europe the average adoption level are 0.67 and 0.65 respectively. In 0 A.D. India and Western Europe catch up with China and the Middle Eastern empires. In 1500 A.D. Western Europe has completed the transition and is the most advanced of the four great empires with an average overall adoption level of 0.94. China remains ahead of most countries with 0.88. The Indian and the Middle Eastern empires have fallen behind to 0.7. Today, the gap between Western Europe and the other three historical empires has widened considerably.

Why do our historical rankings differ from the view that ancient Europeans were barbarians, while China and the Middle East/Islamic civilizations were well in the lead for most of our sample period? Basically, it is for two reasons. First, our measure is more comprehensive and it is less likely to be swayed by highly visible inventions like gunpowder in China. Second, what we are measuring is the adoption of technologies rather than the invention (i.e. by 1500, gunpowder was already adopted in Western Europe and most of the Arab world). Most historians agree that Europe had caught up to and surpassed the Islamic civilization sometime in the late Middle Ages. Appendix 1 details what differences in technology adoption affected the most the rankings.

The usefulness of Table 6 goes beyond describing the relative evolution of technology in the major empires. Because our data collection exercise goes beyond a few case studies, we can put

in perspective the relative dynamics of technology in the empires. In particular, the levels of historical technology adoption reported for the empires in Table 5 until 1500 A.D. are all fairly high. Given the cross-country distribution of technology reported above, this implies that whether Europe is ahead of China or vice-versa is second order compared to the technological advantage of the historical empires compared to most of the rest of the countries in the world.

Underneath the overall technology adoption measures there is significant cross-sectoral dispersion. To explore this, we subtract the country's overall technology adoption from its adoption level in each of the five sectors. Then, we compute the cross-country standard deviation of this variable to measure the within sector variation in technology adoption. Table 6 compares these measures to the cross-country dispersion in the overall technology adoption for each of the three periods we study.

_____ INSERT TABLE 7 HERE _____

The main finding is that the within sector variation in technology adoption is approximately two thirds of the cross-country dispersion in overall technology. In section 4.3, we explore further the implications of this strikingly large heterogeneity in sectoral technology adoption.

A final check we conduct to show that our technology adoption data sets are sensible is to correlate them with the contemporaneous urbanization rate. Several authors¹² have use the urbanization rate as a proxy for development level specially for pre-modern periods such as the ones covered by our technology adoption data set.

_____ INSERT TABLE 8 HERE _____

The urbanization rate for 1000 B.C. and 0 A.D. come from Peregrine's "ACE",¹³ while the urbanization rate for 1500 A.D. come from Acemoglu, Johnson and Robinson (2002). Table 8 reports the estimated contemporaneous effect of overall technology adoption on the urbanization rate. We find that there is a strong and positive contemporaneous association between technology adoption history and the contemporaneous urbanization rates. This provides further support for the quality of our measures of technology adoption in pre-colonial times.¹⁴

3.2 Technology history and current development

We turn next to studying whether centuries-old, pre-colonial technology history is correlated with development today. To answer this question, we estimate the following regression

¹² Acemoglu, Johnson and Robinson (2002), for example.

¹³ Peregrine (2003) constructs a measure of the urbanization rate that can take three values. 1 if the largest settlement is smaller than 100 persons. 2 if it is between 100 and 399 persons. 3 if it is larger than 400 persons.

¹⁴ The working paper version of this article shows that the positive contemporaneous association between overall technology adoption and the urbanization rate is robust to controlling for distance to the Equator.

$$y_c = \alpha + \beta T_c + u_c \quad (1)$$

where current development, y_c , is measured either by the log of PPP adjusted per capita income in 2002 A.D. or by current technology adoption, T_c is the measure of historical technology adoption and u_c is the error term.

_____ INSERT TABLE 9 HERE _____

The first three columns of Table 9 report the estimates of regression (1) when y_c is per capita income in 2002 and T_c is measured successively by the overall adoption level in 1000 B.C., in 0 and in 1500 A.D. (T-statistics are in parentheses.) The technology adoption level in 1000 B.C. is positively and significantly associated with the log of per capita GDP in 2002. Technology adoption in 0 A.D. is not significantly correlated to current development. The overall technology adoption level in 1500 A.D. is positively and significantly associated with current income per capita. This measure of technology in 1500 A.D. explains 18 percent of the variation in log per capita GDP in 2002.

In addition to being statistically significant, the effect is quantitatively large. Changing from the maximum (i.e. 1) to the minimum (i.e. 0) the overall technology adoption level in 1500 A.D. is associated with a reduction in the level of income per capita in 2002 by a factor of 5.

_____ INSERT TABLE 10 HERE _____

The first three columns of Table 10 show that current technology is associated with historical technology adoption very much in the same way as current per capita income. The association between current technology and technology in 1000B.C or 0 A.D. is insignificant. However, there is a strong and significant association between technology in 1500 A.D. and current technology. In particular, changing from the maximum (i.e. 1) to the minimum (i.e. 0) the overall technology adoption level in 1500 A.D. is associated with an increase in the time lag in the intensity of adoption with respect to the US of 22 percent of the years since the invention of the technology.

Figure 2 presents the scatter plot between overall technology adoption level in 1500 A.D. and current development. The positive relationship between these two variables is quite transparent. It is clearly not driven by outliers. In the bottom left quadrant of the plot we can see many African countries that had adopted very few of the technologies in our 1500 sample and that are quite poor today. European countries are in the top right corner.

Countries that roughly correspond to ancient empires such as Egypt, Iran, China, India, and Pakistan were middle-income countries in 2002 and had adopted between 70 and 90 percent of the technologies in our 1500 A.D. sample. These countries are slightly below the regression line in the bottom right quadrant of Figure 2. This paper does not address some well-known puzzles, such as the failure of China to capitalize earlier on its technological prowess, or the stagnation following the earlier technological prowess of the Islamic empire. These are very important puzzles that deserve (and have already attracted) their own literature, but we are concerned here with the global cross-country average relationship between old technology and modern income, and these counter-examples are not numerous enough to overturn the average global relationship.

_____ INSERT FIGURE 2 HERE _____

Latin American countries were behind the median country in the overall technology adoption level in 1500 but today they are middle income countries. This very likely has something to do with the long period of European settlement in Latin America, even though the European settlers were generally a minority of the population. Finally, in the top left corner of Figure 2 we find the Neo-Europes, the US, Canada, Australia and New Zealand. These were among the countries with most primitive technology in 1500 A.D. but are among the World's richest countries today. This is very likely due to the large-scale replacement of the original inhabitants with European settlers.¹⁵

We would expect that the European settlers in the Spanish and Portuguese colonies and in the Neo-Europes affected quite dramatically the process of technology transfer (as well as other factors with which technology may be associated such as human capital accumulation and institutional development) in these countries during the colonial period. Another place where there was large scale (albeit still minority) European settlement was southern Africa. Of course, there could be technology transfer in any colonized nation, but the duration and intensity of the influence of the settlement processes in southern Africa, Latin America and the Neo-Europes suggest adding special controls. European settlement was mainly a function of an exogenous event – the susceptibility of natives to European diseases, which created lightly inhabited fertile lands to be taken over by European settlers (Easterly and Levine 2008). Further, the difference in the degree to which Europeans colonizers substituted for the local population (reflecting differential susceptibility to being entirely wiped out by European diseases) justifies the distinction between the Neo-Europes and Latin America/southern Africa.¹⁶

To formalize this intuition, we use the fraction of European settlers in total population in 1900 from Acemoglu, Johnson and Robinson (2001).¹⁷ This fraction was over 90 percent for the Neo-Europes, between 15 percent and 65 percent for South Africa, Lesotho and Swaziland, and most countries in Latin America and the Caribbean, and below 15 percent for the rest of non-European countries.

Based on this, we create two dummies. The first captures predominant European settlers, and takes a value of one for the US, Canada, New Zealand and Australia and is zero for the rest of the countries. The second dummy reflects lesser European settler predominance than in the neo-Europes, and takes a value of one for the Latin American colonies of Spain and Portugal, South Africa, Lesotho and Swaziland, and is zero otherwise.¹⁸ This yields the following regression equation:

¹⁵ A very similar picture emerges when the dependent variable in current technology adoption as illustrated by Figure A1.

¹⁶ Indigenous mortality from European diseases was a big factor in Oceania and the Americas, but not so much in southern Africa. European settlement in the latter probably reflected the attraction of lightly populated lands in the temperate zones that Europeans preferred (Easterly and Levine 2008).

¹⁷ Similar results are obtained using the share of population from European descent in 1975 from Acemoglu, Johnson and Robinson (2001) or the fraction of European settlers 100 years after first settlement from Easterly and Levine (2006).

¹⁸ Given the small variation in historical technology both within the neo-Europes and within Latin America, including the European influence dummies is equivalent to excluding these countries from the regression.

$$y_c = \alpha + \beta T_c + Major_c + Minor_c + u_c \quad (2)$$

Columns 5 through 7 in Table 9 and Table 10 report the estimates of equation (2) with y_c measured both by per capita income in 2002 (Table 8) and current technology (Table 9) and with T_c measured successively by the overall technology adoption level in 1000B.C., 0 and 1500 A.D.

_____INSERT FIGURES 3,4 AND 5 HERE_____

We find that the European settlement dummies have a significant positive relationship with both current per capita income and current technology. Further, when including the European settlement dummies, the correlation between the overall technology adoption and current development --measured both by per capita income and technology adoption-- increases. In particular, the effects of the technology adoption levels in 1000 B.C. and 0 on current per capita income and technology become statistically significant, and the coefficients approximately double. In other words, once we control for the most obvious historical example of replacement of the indigenous technology by technologies brought by new settlers, technology in ancient times becomes an even more significant predictor of development today.

We acknowledge that there could have been other population migrations that transferred technology, and our singling out of the international European migration may be ad hoc, although it seems to us the primacy of European migration over the last 500 years is not really in doubt.

In any case, our results seem to hold for other population movements as well. We know from a collaborative exercise with David Weil that our findings hold also when we control more comprehensively for the international migration flows. Specifically, we use Putterman and Weil (2007)'s matrix which gives, for each country, the distribution of its current population by its origin. We then pre-multiply the vector of overall technology in 1500 AD by the origin matrix and find that the origin weighted measure of technology predicts current per capita income slightly better than the regressors in column 7 of Table 8. We do not report these results here as Putterman and Weil (2007) have not yet made their data public. Also, we continue to find significant correlations in important specifications (such as those already reported in Table 7) even when the European influence dummies are excluded.

_____INSERT FIGURES 6,7 AND 8 HERE_____

After including the settlement dummies, an increase in the overall adoption level from 0 to 1 in 1000 B.C. or in 0 A.D. is associated with an increase in income per capita in 2002 by a factor of 4. A similar increase in the overall adoption level in 1500 A.D. is associated with an increase in per capita income in 2002 by a factor of 19. This is half of the current difference in income per capita between the top and bottom 5 percent of the countries in the world.¹⁹

After filtering the effect of European influence through the two dummies, the increments in the adoption of current technology associated with having a higher adoption of historical

¹⁹ Table A1 shows the robustness of this finding to using as endogenous variable per capita income in earlier points in time. In particular, the table uses 1913, 1960 and 1990.

technologies are also dramatic. For example, moving from 0 to 1 in the adoption level in 1500 A.D. is associated with a reduction in the adoption lag with the US equivalent to 45 percent of the years since the technology has invented. This is more than twice as much as the observed cross-country standard deviation in current technology adoption.

Similarly, 20 percent of the income difference between Europe and Africa is explained by Africa's lag in overall technology adoption in 1000 B.C., 8 percent is explained by the technology distance in 0 A.D., and 78 percent is explained by Africa's lag in overall technology adoption in 1500 A.D. This gives a very different perspective on Africa's poverty compared to the usual emphasis on modern governments. It also shifts backward in time the historical explanations for Africa's poverty, compared to the usual emphasis of historians on the slave trade and colonialism.²⁰

Figures 3 through 8 display the scatter plots of the two measures of current development (i.e. per capita income -3 through 5- and technology adoption-6 through 8) and overall historical technology adoption after regressing these variables on the European influence dummies. These figures confirm the significant association between current development and historical technology after conditioning on the European influence dummies. Clearly, the strongest relationship holds between overall technology adoption in 1500 A.D. and current development measures.

3.3 Robustness

We explore the robustness of the findings encountered so far. We start by exploring whether we are identifying the effect of historical technology on current development through the cross-continent variation or also through the within continent variation. To answer this question, the first three columns of Table 11 and Table 12 report the estimates of regression (2) when the dependent variable is per capita income (Table 11) and current technology adoption (Table 12) and we add four continent dummies to the control set.

We extract two main conclusions from columns 1 through 3. First, much of the effect of technology history is detected from the cross-continent variation. Adding the continent dummies eliminates the effect of overall technology adoption in 1000 B.C. on current development (column 1), and reduces, approximately, by 60 percent the effect of technology adoption in 0 A.D. (column 2) and in 1500 A.D. (column 3) on current development. Only 1500 AD is still significant. The flip side of this is that a significant fraction of the effects of technology adoption history in 0 A.D. and 1500 A.D. on current development is driven by the within continent variation. In particular, the within continent variation in overall technology adoption in 1500 A.D. can still account for cross country variation in current income per capita by a factor of 4.5 and for about one standard deviation of the observed cross-country dispersion in current technology adoption.²¹ In sum, the persistence of technology across the last 500 years, or the last 2000 years, is not just due to differences between continents.

²⁰ There was some slave trade before 1500 A.D. across the Sahara and along the Indian Ocean. However, most accounts of the negative effects of the slave trade stress the Atlantic slave trade, which only became nontrivial after 1500 A.D.

²¹ One interesting question is whether the effect of historical technology on current development works through a positive effect on total GDP or through a negative effect on current population. In the working paper we show that the relationship works entirely through the effect of technology on GDP. Indeed, historical technology also has a

_____ INSERT TABLE 11 HERE _____

Gallup, Sachs and Mellinger (1999) have argued that the latitude is an important determinant of income per capita, with the tropics at a disadvantage. Hall and Jones (1999), Acemoglu, Johnson, and Robinson 2002, Easterly and Levine 2003 and Rodrik et al. (2003) argue that the effect of tropical location is through institutions. In principle, there is no reason for these effects to be linear. Columns 4 through 6 in Table 11 and 12 report the estimates of regression (2) after controlling for the distance to the Equator both with a linear and a quadratic term.²² As emphasized by the previous literature, being very far from the Equator tends to be associated with higher levels of current technology and income per capita. Controlling for the latitude of countries, however, does not eliminate the strong positive effect of overall technology adoption in 1500 A.D. on current development. This effect remains statistically significant, though the association of technology adoption history on 1000 B.C. and in 0 A.D. on current development become insignificant after controlling for the distance to the Equator.²³ In columns 7 through 9 we additionally control for whether countries are land-locked reaching the same conclusions as in columns 4 through 6. In columns 10 through 12, we further experiment with a tropical dummy (and the land-locked dummy) showing that the results on 1500 AD -both for current income and technology- are robust to this geographic control.

Hence, our robust finding is that 1500 AD matters for current development, while the results on 1000 BC and 0 AD mattering for today's development are not robust. We still have the result that there is persistence in technology in the more ancient periods -- from 1000 BC to 0 AD, and from 0 AD to 1500 AD -- but the variation in technology unexplained by persistence over each long epoch is high enough to make the direct link from 1000 BC to the present much weaker (not so surprisingly!) than the link from 1500 AD to the present.

_____ INSERT TABLE 12 HERE _____

An interesting question is why the geography controls reduce the significance of historical technology adoption on current development. Of course, there are many possible explanations for this observation. One consistent with the model presented in section 4 is that geography affects the diffusion of technologies. Technologies diffuse faster within than across continents. Diamond (1997) advanced the hypothesis that certain technologies diffuse along latitudes. Finally, landlocked territories may be less exposed to newer technologies and hence adopt them later and/or less intensively.

_____ INSERT TABLE 13 HERE _____

As we have noted above, the association between land area and ancient technology could be reverse causality, since a larger land area contained a larger sample of cultures and technologies from which we are coding the "best." We conclude, however, that this is not a very significant

strong and robust relationship with current population, but the effect on current GDP is so large that more than compensates the effect on population.

²² The results are extremely robust to all sort of polynomials in the latitude.

²³ Similar results hold when including a tropical dummy instead of the distance from the Equator.

concern based on two results reported in Table 13. First, per capita GDP today and current technology are uncorrelated with land area. Second, the correlation between historical technology adoption and, both, per capita GDP today and current technology remain unaffected by the land area control. So the association between contemporaneous technology and land area does not seem to reflect any dominant “sampling” effect.

4. A model of endogenous technology adoption and discussion

We next present a model that provides a simple rationalization for the facts uncovered so far. The model is also an effective tool to help us think about alternative hypothesis and how to identify them in the data.

4.1 Baseline model

Generations are indexed by t . Countries are indexed by c . Let A_{ct} denote the number of technologies adopted up to t . The representative agent in the country lives for one generation and decides how many new technologies to adopt during that period. The (gross) value he obtains from adopting ΔA_{ct} new technologies technology is

$$\pi_{ct} = \bar{\Theta}_{ct} \Delta A_{ct} \quad (3)$$

where $\bar{\Theta}_{ct}$ is a potentially time-varying parameter.

The cost of adopting new technologies is given by the following function.

$$C_{ct} = b_{ct} \frac{(\Delta A_{ct})^\gamma}{A_{ct-1}} \quad (4)$$

where b_{ct} may be time-varying and $\gamma \in [1, \infty)$ implying that the cost is increasing and convex in the number of new technologies adopted in the period. Note that, in this formulation, the cost of adoption declines with the stock of technologies previously adopted in the country. This is the case both because existing technologies reduce the physical cost of adopting the new technologies and because adopters learn from previous adoption experience. This learning may be formal (e.g. training) and/or informal (e.g. trial and error) but as a result of it, technological leaders are the first to adopt new technologies. See our discussion of all the mechanisms by which this effect could operate in Table 1 (although some of the mechanisms in Table 1 have to do with the benefit of the new technology, which could be easily incorporated in our model as an effect of initial technology on value rather than cost of adoption).^{24,25}

²⁴ We have also developed an extended version of the model that allows for cross country differences in the technology frontier. This extension permits us to capture country interactions and the effect of international migration and colonization. This generalization of the model could also account for the great divergence during the XIX century. All the testable implications of the simpler model go through in this more general version. The Generalization is available upon request from the authors.

²⁵ Our stylized model ignores the intensive margin of adoption (i.e. how many units of the technology are adopted in the country). This is not a bad approximation up to approximately 1875, since the extensive margin accounts for a very significant share of the cross-country variation in adoption. It is easy to see, however, how a similar argument to the one made above helps explain cross-country variation in the intensive margin of adoption in more recent times. (That is, the cost of adoption faced by individual adopters declines with the stock of technologies they adopted in the

Optimal adoption of new technologies yields the following law of motion for A_{ct} .

$$\frac{\Delta A_{ct}}{A_{ct-1}} = \left(\frac{\Theta_{ct} A_{ct-1}^1}{A_{ct-1}^{\gamma-1}} \right)^{\frac{1}{\gamma-1}} \quad (5)$$

where

$$\Theta_{ct} \equiv \frac{\bar{\Theta}_{ct}}{\gamma b_{ct}} \quad (6)$$

It is quite clear from (5) that the long run dynamics of technology depend on the value of γ . Suppose for simplicity that Θ_{ct} is stationary. Then if γ is smaller than 2, the number of technologies adopted grows at an accelerating rate as technology level rises in the long run. This would also apply across countries, so that more advanced countries will have faster growth and there will be divergence. If γ is equal to 2, A_{ct} grows endogenously in the long run at a stationary rate; there is technological persistence but neither convergence nor divergence. Finally, if γ is greater than 2, A_{ct} grows at a decreasing rate in the long run as technology rises. Less advanced countries will grow faster than more advanced countries and there will be convergence.²⁶

One interesting feature of an accelerating growth model for certain parameter values is that the acceleration can be extremely gradual for long periods, but then when A gets sufficiently high, growth can suddenly accelerate very rapidly. Figure 9 shows a simulation of equation 5 in which growth is virtually nonexistent for millennia and then spikes up to modern growth levels over the last two centuries.²⁷ Another more backward area with lower initial technology (assumed to be half of the initial technology of the more advanced area) would not have this spike. So our simplistic toy model could account for both the acceleration of growth with the industrial revolution of the last two centuries and the great divergence between countries over the same period! Of course, we don't take this entirely seriously, but we think it is a cute illustrative demonstration of the potential power of technology propagation models. (Two big reasons not to take this exercise too seriously: (1) as is well known in the new growth literature, increasing returns quickly becomes an embarrassment as growth will keep accelerating to absurd levels. If the model is to be rescued, there must be something else that slams the brakes on further increases in growth once it reaches modern growth rate levels, such as a limit on how many new technologies can be absorbed per unit of time relative to existing technologies. (2) Our actual estimates of γ discussed below show it to be very close to 2.

To make further progress, it is useful to rewrite (5) using the log approximation around the deterministic steady state as follows:

$$a_{ct} = \frac{1}{\gamma-1} \theta_{ct} + \frac{1}{\gamma-1} a_{ct-1} \quad (7)$$

past.) The model also ignores other micro aspects of the adoption decision that may not be of first order importance to understanding the adoption dynamics such as who is the adopter, a firm, a person, the government,...

²⁶ Note that, our model has two ways of generating the observed acceleration of the growth of the world frontier: having

$\gamma > 2$ or an increase in Θ_{ct} .

²⁷ The parameter values are $\Theta_{ct} = .14$, $\gamma = 1.5$, and initial $A = .0165$. We experimented with different parameter values until we found an example like that shown in Figure 9.

where $\theta_{ct} \equiv \log(\Theta_{ct})$ and $a_{ct} \equiv \log(A_{ct})$.

Iterating (7) back in time we obtain

$$a_{ct} = \sum_{\tau=1}^t \theta_{ct-\tau+1} \left(\frac{1}{\gamma-1} \right)^\tau + \left(\frac{1}{\gamma-1} \right)^t a_{c0} \quad (8)$$

We further assume that $\theta_{ct} = \alpha \theta_{ct-1} + \varepsilon_{\theta ct}$, where $E_0 \varepsilon_{\theta ct} = 0$, for $t > 0$. Then, it follows that the expected level of technology adopted at t given the adoption history up to time 0 is

$$E_0(a_{ct}) = \frac{\alpha}{\gamma-1} \frac{\alpha^t - \left(\frac{1}{\gamma-1} \right)^t}{\alpha - \frac{1}{\gamma-1}} \theta_{c0} + \left(\frac{1}{\gamma-1} \right)^t a_{c0} \quad (9)$$

To derive the relationship between historical technology and current per capita income, we just need to assume that, at least in modern times, per capita income is determined by contemporaneous technology.²⁸ Formally,

$$y_{ct} = a_{ct} \quad (10)$$

Hence,

$$E_0(y_{ct}) = \frac{\alpha}{\gamma-1} \frac{\alpha^t - \left(\frac{1}{\gamma-1} \right)^t}{\alpha - \frac{1}{\gamma-1}} \theta_{c0} + \left(\frac{1}{\gamma-1} \right)^t a_{c0} \quad (11)$$

This simple model delivers three testable predictions. First, since 't' is very large in our sample, the coefficient of a_{c0} in (11), can help us calibrate γ . In particular, the coefficient, $\left(\frac{1}{\gamma-1} \right)^t$,

tends to 0 if $\left(\frac{1}{\gamma-1} \right) < 1$. (That is, if $\gamma > 2$.) Similar, this coefficient should be very large, and in

particular greater than 1, if $\left(\frac{1}{\gamma-1} \right) > 1$. (That is if $\gamma < 2$.) Finally, the coefficient of a_{c0} in (11) can

only be between 0 and 1 if $\left(\frac{1}{\gamma-1} \right) \approx 1$. (That is if $\gamma \approx 2$.)

Second, equation (9) implies that, if $\left(\frac{1}{\gamma-1} \right) \approx 1$, there is persistence in technology adoption.

One implication of this is that the technology adoption history helps predict current technology adoption. Third, the reason why technology adoption history can predict current development is

²⁸ This might not have been the case in pre-industrial societies where population is determined by Malthusian dynamics as in Kremer (1993), Galor and Weil (2000), Prescott and Hansen (2002) and Jones (2001, 2005), but it is a very reasonable assumption for modern societies supported by the findings in Comin and Hobijn (2008).

because it can predict current technology. Therefore, after controlling for current technology historical technology adoption should not help us forecast current development.²⁹

These predictions can easily be tested with our data. We have already observed in Tables 9 and 11 that overall technology adoption in historical periods predicts current technology. To explore further whether technology is persistent, we estimate the cross-country correlation of technology adoption across the historical time periods.

_____ INSERT TABLE 14 HERE _____

As reported in Table 14, the correlation of the overall technology adoption level between 1000 B.C. and 0 is 0.62, between 0 A.D. and 1500 A.D. it is 0.71 and between 1000 B.C. and 1500 A.D. it is 0.68. (It is also reassuring that the error rate on our technological measures is not disastrously high.)

We find instructive to make a quantitative assessment of this persistence. If 't' is measured in years, the autocorrelations estimated in the first column of Table 14 imply that when calibrated annually, $\left(\frac{1}{\gamma - 1}\right) \geq 0.9995$.

We also observe this high persistence of technology adoption for the sector-level measures. The average correlation coefficient between the technology adoption in a sector in one period and in the subsequent period is around 0.5. Technology adoption is most persistent in military, industry and transportation. The lowest correlation is in communications between 1000 BC and 1500 AD. This latter correlation is still statistically significant at the 5 percent level. All the other correlations reported in Table 14 are significant at the 1/10000 level.

_____ INSERT TABLE 15 HERE _____

As shown in Tables 12 and 15, this persistence of technology adoption is not driven by the geographical variables since it holds once we control for the continent, the latitude and whether the country is landlocked.

_____ INSERT TABLE 16 HERE _____

We conclude this exploration of the model predictions by investigating the third prediction, namely that the effect of historical technology adoption on current development operates through current technology adoption. Table 15 shows the strong positive association between current technology and per capita income in 2002. The R² in this regression is 80 percent. The

²⁹ There is a fourth interesting prediction which we cannot test due to lack of data which is that, if technology is so persistent that $\left(\frac{1}{\gamma - 1}\right) \approx 1$, factors that affect the historical return to adopting the technology (i.e. institutions) may also affect current development even if institutions are not persistent and even after controlling for historical technology. This is the case because such factors affect the change in technology at time 0, hence affect the level of technology (at least shortly) after 0 and hence affect subsequent technology adoption.

importance and significance of this variable is robust to controlling for the distance to the equator and for the continent dummies.

In columns 4 through 8 of Table 16 we include our measure of overall technology adoption in 1500 AD as an additional control. However, its association with current development becomes insignificant once we control for current technology. This is the case even after including the European influence dummies (columns 7 and 8). Since technology 1500 AD was robust and significant in our previous regressions, we interpret this finding as evidence that the effect of historical technology on current development operates most robustly through the effect that historical technology adoption has on current technology adoption.

4.2 Population

One interpretation of the findings so far is that technology is a very powerful propagation mechanism. That is, a variety of factors (e.g. institutions, geography shocks, luck,...) affect the return to adopting technology in the distant past and those historical technology adoption levels are propagated into the present through the effect that technology has on the agent's incentives to adopt subsequent technologies.

An alternative view, also consistent with the model presented above, is that the powerful propagation mechanism is not the dynamics of technology adoption but the dynamics of the return to adopting technology (θ_{ct}). That is, rather than having $\left(\frac{1}{\gamma-1}\right) \approx 1$, the persistence of historical adoption results from $\alpha \approx 1$.

One variable that has been linked to improved technology is population. Kremer (1993) develops models where this is the case because more population means more inventors of ideas. Similarly, semi-endogenous growth models (e.g. Jones (1995,1999, 2001, 2005), Kortum (1997), Segerstrom (1998)) also have the feature that the force that ultimately keeps technology improving is the continuous expansion of the scale in the economy through population growth. The reduced form of these models in technology alone would also predict technological persistence, and so this fact alone is not enough to assess the weight to be attached to different models.

These models stress the effect of population through the supply of ideas with the increased number of thinkers. We can generate a similar population effect by having population affect our return to ideas (as it obviously does with non-rival ideas). Our simple model can accommodate these insights by assuming that $\theta_{ct} = l_{ct}$, where l_{ct} is the log population and evolves according to $l_{ct} = n_c + l_{ct-1} + \varepsilon_{lct}$, $E_0 \varepsilon_{lct} = 0$, for $t > 0$. Then, a_{ct} can be expressed as:

$$a_{ct} = \sum_{\tau=1}^t \left(n_c (t - \tau + 1) + l_{c0} + \sum_{q=1}^{t-\tau+1} \varepsilon_{lct} \right) \left(\frac{1}{\gamma-1} \right)^\tau + \left(\frac{1}{\gamma-1} \right)^t a_{c0} \quad (12)$$

Over the long horizons we consider in this paper, $n_c \approx \frac{l_{ct} - l_{c0}}{t}$. Hence, (12) implies

$$E_0(a_{ct}) = \left[\sum_{\tau=1}^t \frac{(t-\tau+1)}{t} \left(\frac{1}{\gamma-1} \right)^\tau \right] (l_{ct} - l_{c0}) + \left(\frac{1}{\gamma-1} \right)^t a_{c0} + \frac{1 - \left(\frac{1}{\gamma-1} \right)^t}{\gamma-2} l_{c0} \quad (13)$$

Expression (13) implies that if $\left(\frac{1}{\gamma-1} \right) < 1$, historical technology should not predict current technology once we control for historical and current population. Further, failing to control for current and past population in our regressions may cause an upward bias in our estimate of $\left(\frac{1}{\gamma-1} \right)$ if the return to adopting technology, θ_{ct} , is higher in larger countries.

To identify whether the observed persistence of technology is driven by the omission of population in our regressions or because technology has a direct propagation mechanism, we control for historical and current population in our baseline regression (2). As we show in the appendix, this identification strategy is valid regardless of the influence from other countries technology in the adoption cost. Table 17 and 18 report the estimation results .

_____ INSERT TABLE 17 HERE _____

The first three columns of Table 17 report the effect of technology and population in 1500 AD on current per capita income (column 1), current technology (column 2) and current population (column 3). The main finding is that the observed effect of historical technology on current development and current technology is robust to controlling for historical population. Indeed, the effect of historical population on current development is negative and significant. Both historical technology and population have positive significant effects on current population, although the significance of historical population is much higher.

We conduct similar exercises with technology (column 4) and population (column 5) in 1500 AD as dependent variables and technology and population in 0 as independent variables. Our findings are very similar to those reported in the first three columns of Table 17. For example, the effect of technology adoption in 0 on technology in 1500 persists after controlling for population in 0.

_____ INSERT TABLE 18 HERE _____

Expression (13) implies that to identify the propagation mechanism that generates the persistence of technology, we should control both for historical and for current population. Table 18 conducts this more proper test by including current population as control. Regardless of whether we use current development (column 1) or technology (column 2) as dependent variables, we still find that technology in 1500 AD has a strong and significant effect on current outcomes. Current population has a negative and significant effect on current development and technology. Population in 1500 has an insignificant effect. A shortcoming of this exercise is the endogeneity of current population, which we do not have a good means of addressing because of a lack of any obvious instrument.

In columns 3 and 4 of Table 18 we control further for the continent dummies. This reduces the magnitude of the coefficients but the effect of technology adoption in 1500 on current development and technology still remains significant.

We are inclined to interpret our findings as supporting a direct effect of old technology on new technology, even controlling for the population channel. We don't claim to have refuted the population and technology model, since our coefficients on population are all over the place and usually insignificant; we think a more detailed test of the many predictions of the population and technology models would be needed to pass judgment on those models. For now, we conclude at a minimum that population dynamics are not the ONLY propagation mechanism that generates the observed effect of technology adoption history on current development.

4.3 Institutions, culture, genes

The literature has emphasized at least three more variables that are likely to affect the return to adopting technology and could be driving the observed persistence of technology. These are institutions, culture and genetics. If any of these variables affects historical technology adoption and is sufficiently persistent, its omission from our regression will bias the estimate of $\left(\frac{1}{\gamma-1}\right)$ and could rationalize the facts presented so far.³²

Further progress can be made in the estimation of $\left(\frac{1}{\gamma-1}\right)$ if we assume that, the effect of institutions, culture and genetic endowment on the return to technology adoption has an important symmetric component across sectors. That is, good institutions preserve property rights and induce agents to adopt new technologies in all sectors (covered by our data set).³³

Under this sensible assumption, we can estimate $\left(\frac{1}{\gamma-1}\right)$ by exploiting the large observed within sector variation in technology adoption (see Table 6). This intuition is formalized with the following multi-sector extension of our baseline model.

Suppose that the profits and costs from adopting ΔA_{cst} new technologies technology in sector s are, respectively

$$\pi_{cst} = \bar{\Theta}_{cst} \Delta A_{cst} \tag{14}$$

³² Common measures of institutions do not seem to be sufficiently persistent to cause any significant bias. Przeworski (2004) has calculated that the correlation of 'constraints on executive' for 59 countries from Polity IV from first year of independence to most recent year available is only .26. Similarly, we have estimated the cross-country correlation in the democracy variable from Polity IV in 2000 with the same variable in 1950 to be .33. It seems remarkable that these widely used measures of institutions are less persistent over a 50-year period than technology adoption over a 2500 year period. However, this is only one measure of institutions, and "deeper" measures of institutions may show much more persistence. If institutions really do have low persistence, omitting historical

institutions from our baseline regression should not bias our estimate of $\left(\frac{1}{\gamma-1}\right)$.

³³ Similarly, the forces by which culture and genes affect technology adoption (e.g. higher willingness to experiment or higher I.Q.) are relevant to all the sectors covered in our data sets.

$$C_{cst} = b_{cst} \frac{(\Delta A_{cst})^\gamma}{A_{cst-1}} \quad (15)$$

Note that in this formulation, the cost of adoption declines in the level of technology adopted in the sector. Then the optimal adoption of technology in sector s and country c implies the following law of motion for technology.

$$\frac{\Delta A_{cst}}{A_{cst-1}} = \left(\frac{\Theta_{cst} A_{cst-1}}{A_{cst-1}^{\gamma-1}} \right)^{\frac{1}{\gamma-1}} \quad (16)$$

where

$$\Theta_{cst} \equiv \frac{\bar{\Theta}_{cst}}{\gamma b_{cst}} = \Theta_{ct}^I * \Theta_{cs}^S * \Theta_{cst}^S \quad (17)$$

Let $\theta_{cst}^S \equiv \log(\Theta_{cst}^S)$ be a zero mean, iid, term, $\theta_{ct}^I \equiv \log(\Theta_{ct}^I) = \alpha \theta_{ct-1}^I + \varepsilon_{1ct}$, where $E_0 \varepsilon_{1ct} = 0$ for $t > 0$ and $\theta_{cs}^S \equiv \log(\Theta_{cs}^S)$. Note that, in this formulation, θ_{ct}^I captures (potentially time-varying) factors that affect the return to adopting technology in all sectors, θ_{cs}^S reflects fixed factors that affect the return to adopting technology in sector s of country c , and θ_{cst}^S captures other factors that affect the return to adopting technology.

$$a_{cst} = \sum_{\tau=1}^t \left(\theta_{ct-\tau+1}^I + \theta_{cs}^S + \theta_{cst-\tau+1}^S \right) \left(\frac{1}{\gamma-1} \right)^\tau + \left(\frac{1}{\gamma-1} \right)^t a_{cs0} \quad (18)$$

and

$$E_0(a_{cst}) = \left[\frac{\alpha}{\gamma-1} \frac{\alpha^t - \left(\frac{1}{\gamma-1} \right)^t}{\alpha - \left(\frac{1}{\gamma-1} \right)} \right] \theta_{c0}^I + \left[\frac{1 - \left(\frac{1}{\gamma-1} \right)^t}{1 - \left(\frac{1}{\gamma-1} \right)} \right] \theta_{cs}^S + \left(\frac{1}{\gamma-1} \right)^t a_{cs0} \quad (19)$$

The empirical counterpart to equation (19) is

$$a_{cst} = \beta_{ct-1} + \beta_{cs} + \mathcal{G}^* a_{cst-1} + u_{cst} \quad (20)$$

This regression includes a country effect (β_{ct-1}) that could be time-varying and a country-sector fixed effect (β_{cs}). The identification of \mathcal{G} presents the well-known challenge often encountered in convergence regressions of a lagged dependent variable. To solve this problem we first difference equation (20) obtaining

$$a_{cst} - a_{cst-1} = \beta_{ct-1} - \beta_{ct-2} + \mathcal{G}^* (a_{cst-1} - a_{cst-2}) + \bar{u}_{cst} \quad (21)$$

and instrumenting $a_{cst-1} - a_{cst-2}$ with a_{cst-2} . If a_{cst-2} is uncorrelated with \bar{u}_{cst} our estimate of \mathcal{G} will be unbiased. We are going to implement regression (21) with $t = 2000$ AD, $t-1 = 1500$ AD and $t-2 = 0$ AD. We find it sensible that $\bar{u}_{cst} \equiv u_{cs2000} - u_{cs1500}$ is uncorrelated to the technology adoption level in 0 AD (i.e. 1500 years before).

In our list of current technologies we have no military technology. Hence, we estimate (21) using data on the other four sectors in our data set. Since, from our previous results, the European influence will have an effect on the growth of technology between 1500 and 2000, we control for the two European influence dummies when estimating \mathcal{G} in (21).

Table 19 reports the estimates of ρ with (column 1) and without (column 2) the country fixed effects in the growth rates. The main finding is that we observe very large and significant estimates of ρ in both specifications. There are several important implications from these estimates. Recall that both of these regressions include country fixed effects in levels and country-sector fixed effects in levels. This is suggestive that persistent factors that have remained constant over the last 500 years and which may or may not have affected asymmetrically technology adoption in the country - such as genes or geography- are not the primary drivers of the estimates of the persistence of technology (i.e. ρ).

A second interesting observation is that the estimates of ρ are virtually unaffected by the inclusion of the country (time-varying) effects. These terms capture changes at the country level between 1500 and 2000 which affect symmetrically the adoption of technology across sectors (within the country), such as an improvement in institutions (see Jones 2001). Including these country effects in the regressions does not affect the size of our estimate of ρ (indeed it increases). Our results say that if a technology in one sector in one country improves more than average country-wide technological improvement in 1500, that technological improvement shows up in better technology in that sector (relative to the country-wide average) in 2000. This is suggestive that omitted time-varying factors that affect the adoption of technology in many sectors in the economy – such as an improvement in institutions – are not solely responsible for the observed high persistence in technology adoption.³⁴ Note that this argument stands even if the omitted variable has a differential effect across sectors as long as it has a significant common component. We take this as very supportive of our hypothesis that there is a direct effect of old technology on new technology adoption, even if institutional and other country-wide factors also matter.

Because of potential cross-technology differences in diffusion not captured by our model, we explore the robustness of our estimates of ρ to including technology-specific intercepts. As is clear from columns (3) and (4) of Table 19, the significance of ρ is unaffected. Interestingly, the similarity of the point estimates with and without country (time-varying) effects also persists after including technology-specific intercepts.

We conclude our empirical exploration of the sources of persistence in technology adoption by showing that the significance of ρ is not driven by any single sector. In columns 5 through 8 of Table 19 we report the estimates of ρ after eliminating successively one of the four sectors covered in our data set -recall that we have excluded the military technologies from this analysis.

Two observations emerge from this exercise. First, the significance of the estimate of ρ is not driven by any specific sector. Second, when comparing the estimates of ρ obtained by exploiting the sectoral variation in technology adoption (e.g. columns 3-8 of Table 19) with the estimates we obtained when using the cross-country variation (e.g. columns 3, 6, 9 and 12 of Table 12) it turns out that the former are not smaller than the later.

³⁴ We do not know whether the aspects of culture which are relevant for adoption of technology are fixed over a 500 year period or time varying, but in either case, they are also likely to be taken care off by one of the two arguments posed above.

As argued above, this is hard to reconcile with theories where the ONLY mechanism that induces the persistence of technology operates at a country-wide level. Instead, this observation can be accounted for naturally by our simple theory since the knowledge created when adopting a technology in a given sector is likely to reduce the costs of adopting subsequent technologies in the sector but not so much in other sectors.

Hence, we are inclined to conclude from the findings presented in this paper that the dynamics of technology adoption are a direct propagation mechanism that transmits significant technology shocks of very diverse nature into the distant future. The primary feature of our model that predicts this result is that the cost of technology adoption is lower the higher is the previous stock of technology.

5. Conclusions

The main finding of this paper is a simple one: centuries-old technological history is associated with the wealth of nations today. This is largely robust to including continent dummies and geographic controls, so it is not just driven by “Europe vs. Africa” or “tropical vs. temperate zones.” There are two surprising parts of the finding. The first is just how old the history can be and still be correlated with modern outcomes. Our most robust finding is that technology in 1500 AD is correlated with development outcomes today, itself remarkably old when we consider that most history discussions of developing countries start (at most) with European contact and colonization. The second surprising aspect of our finding is how large is the magnitude of the association between historical technology adoption and current development. In our baseline specification, going from having none to having adopted all the technologies available in 1500 AD is associated with an increase in current per capita GDP by a factor of 17. Even after including a battery of controls, this factor is over 5.

In an effort towards understanding what drives this surprising correlation, we have found suggestive results that technology is very persistent, that this persistence is not driven only by the persistence of population, and that it does not diminish when exploiting the sectoral variation in technology adoption after removing the country average adoption level in the period and country-sector fixed effects (hence controlling for any factors that operate at a country-wide level such as institutions). This evidence provides support to the hypothesis that the technology adoption dynamics -- in which the cost of adopting new technology falls with the stock of previous technology -- are the mechanism that generates the propagation uncovered in the data.

Appendix 1

In Table 5 we document the progression of advanced civilizations (Western Europe, China, India, and the Arab Empire) from 1000 BC to 1500 AD. Initially Western Europe lagged behind other civilizations but assumed technological leadership by 1500 AD. Western Europe initially started as the least technological sophisticated of the major advanced civilizations in 1000 B.C. It's lowly position was due to its slower adoption of communications, transportation, and military technology. Western Europe, with the exception of Italy, had not yet adopted written records for communication, vehicles for transportation, and iron weapons. Other advanced civilizations at the time, such as China and the Arab Empire already were using these technologies. However, by 0 A.D. Western Europe had adopted these technologies, and by 1500 A.D. it was the most technologically advanced civilization. Western Europe's ascendancy is primarily due to advances in transportation and military technology. During the 16th century, Western Europe alone had expeditions across all major oceans (The famous Chinese explorer Cheng Ho had voyaged across the Indian Ocean as far as East Africa in 1405-1431, but these voyages turned out to be an aberration as the voyages were stopped and ships destroyed by a subsequent emperor) . These journeys required adopting a number of shipbuilding and navigational technologies. Western Europe also was at the forefront in naval weapons. The navies of Western Europe deployed large warships (in excess of 1500 ton deadweight) with armaments of over 180 guns by the 16th century. Even advanced civilizations such as China and the Arab Empire had not yet adopted these advanced weapons.

Mechanism for technology persistence	Examples from economic history literature
<p>Complementarities between existing technology and new technology (CT is “complementary to”) If a new technology is complementary to an old technology, then the cost of adopting the new technology is lower. The more technologies in the initial technology set, the more new technologies there will be that are complementary.</p>	<p>Cement masonry CT roads and aqueducts under Romans (Mokyr 1990, pp. 19-20), Roman water lifting CT power transmission (gears, cams, chains) (Mokyr 1990, p. 21), medieval waterwheels CT grain mills (Rosenberg and Birdzell 1986, p. 154), medieval heavy plow CT fallow system CT draft animals feeding on fallow and fertilizing field CT horse collar and nailed horseshoe (Mokyr 1990 pp. 32-35), compass CT astrolabe CT advances in astronomy CT oceangoing ships in 15th century (Mokyr 1990, p. 47, Rosenberg and Birdzell pp. 72, 84), metallurgy CT Gutenberg press (Mokyr 1990, p. 48), new crops alfalfa and clover CT stall feeding of livestock CT animal fertilizer and abandonment of fallow system 1500-1750 (Mokyr 1990, p. 58) Chain mail CT breastplates and armor for soldiers (Rosenberg and Birdzell 1986, p. 58), Textile machinery CT Chemical innovation on detergents, bleaches mordants, and dyes (Landes 1969, p. 108)</p>
<p>Recombination of old technologies to make new technology. Many new technologies are novel combinations of old technologies. The greater the number of old technologies, the greater the number of possible combinations to make new technologies.</p>	<p>“the lever , the wedge and the screw , ... the ratchet , the pulley , the gear , and the cant” used to make Greek/Roman war machines (Mokyr 1990, p. 21), salt preservation of meat and improved transportation in 15th century = long distance trade in cattle from rural areas to cities (Rosenberg and Birdzell 1986, pp. 75-76), steam power + iron and steel metallurgy = factory machines (Rosenberg and Birdzell 1986, p. 146), steam engine + rails = railroad, refrigeration + steamships = long distance meat exports to Europe, electricity generation + conductors + meters + lamps = electric light (Rosenberg 1982, pp. 58-59), germ theory+ bactericidal molds + mass chemical production = penicillin (Mokyr 2002, p. 107) internal combustion engine + glider + propeller=airplane (Mokyr 2002, p. 114)</p>
<p>Feedback from technology to science. When techniques “work,” this gives new evidence to scientists to test theories why they work. Science will in turn be used to make further innovations in technique. “Science” should be defined very broadly beyond formal science to include general understanding of “laws of nature” or “the way the world is,” making statements that are true or false. Technology is defined as the toolkit of “techniques,” which are not “true or false,” but simply “work.”</p>	<p>Working machines to Galileo’s general theory of machine principles (Mokyr 1990, p. 75), Steam engine to thermodynamics (Mokyr 1990, p. 90; Rosenberg 1982, p. 14), food canning to bacteriology and germ theory of disease (Rosenberg and Birdzell 1986, p. 245), Wright brothers to aerodynamics (Mokyr 2005, Mokyr 2002, pp. 96-97) Rosenberg 1982, p. 157), discovery of transistor to field of solid-state physics (Rosenberg 2000, p. 33), telegraph to mathematical physics (Mokyr 2002, p. 90)</p>
<p>Feedback from technology to lower access costs for knowledge. The more advanced are certain “access” technologies, the easier it is to obtain general scientific knowledge, which then lowers the cost of innovation and adoption.</p>	<p>Greek/Roman alphabetization, Arabic numerals, Gutenberg printing, 19th century innovation in paper and printing, lower transport costs for people and books, postal services, standard weights and measures, encyclopedias, ICT revolution (Mokyr 2002)</p>

Table 1 (continued): Mechanisms for persistence of technology from economic history literature	
Spillover of technology from one sector to another. Technological ideas from one sector inspire new approaches to problems in other sectors.	Clockmaking and watchmaking beginning with medieval town clocks spillover to precision machining for factories in industrial revolution (Rosenberg and Birdzell 1986, pp. 148-150), Steam engine inventor Watt's background was in mining industry, which required knowledge of metallurgy, chemistry, mechanics, and civil engineering (Mokyr 1990 p. 162); spillover from petrochemical industry for auto fuel to plastics and synthetic fibers (Rosenberg 2000 p. 92)
Economies of scale. Some technologies have fixed costs or internal economies of scale such that it is only worth adopting them at higher scale of operation of the economy. The greater is initial technology, the greater the scale of operation of the economy.	Larger oceangoing ships and expanding world trade in 15 th century (Rosenberg and Birdzell 1986, pp. 82-83), Mechanical reaper (David 1975), Assembly line and interchangeable parts (Mokyr 2002)
Economies of scope of General Purpose Technologies. When a GPT is invented, it's payoff is greater, the more technologies in which it can be used. Hence the greater is initial technology, the greater the payoff to a GPT.	Gutenberg printing press, Ocean-going ships in 15 th century, Electric engine for factories in virtually all sectors and multiple home appliances (Rosenberg 1982, pp. 78-79), ICT (Mokyr 2002, pp. 112-113)
Feedback from technology to improved lab equipment. Improved lab equipment lowers the cost of scientific discovery, innovation, or adoption. The better is existing technology, the better the lab equipment.	Medieval optics made possible telescope and microscope (Rosenberg and Birdzell 1986, p. 58), instruments measuring time, distance, weight, pressure, temperature, Volta's battery, Petri dish (Mokyr 2005) advances in lens grinding to make better telescopes and microscopes (Mokyr 2002, pp. 97-100)
Learning by doing. Much of technological progress consists of learning how to make old techniques work better through small adjustments, minor innovations, and adaptation to local circumstances.	Ocean-going ships since 15 th century improved sailing efficiency and ship design until advent of steam power (Rosenberg and Birdzell p. 263), coal required to generate kilowatt-hour of electricity fell drastically over the decades; semiconductors moved from a single transistor on a chip to more than a million such components (Rosenberg 1994, pp. 14-15), high pressure steam engine design and transmission (Mokyr 2002, p. 84); transition from Bessemer to Siemens Martin steelmaking process (Mokyr 2002, pp. 86-87)

Table 2: Coding Concordance Between “ACE” and the Technology Adoption Dataset

“ACE” Dataset	Technology Dataset for 1000 B.C. & 0 A.D. (0 = indicates absence of technology, 1 = presence of technology)
Writing & Records	Communication
1 = None	
2 = Mnemonic or nonwritten records	0,1
3 = True Writing	0,1
Technological Specialization	Industry
1 = None	
2 = Pottery	0,1
3 = Metalwork (alloys, forging, casting)	0,1
Land Transport	Transportation
1 = Human Only	
2 = Pack or draft animals	0,1
3 = Vehicles	0,1
Agriculture	Agriculture
1 = None	0
2 = 10% or more, but secondary	1
3 = Primary	2
Military	Military
1 = Stone Tools	
2 = Bronze Tools	Bronze weapons: 0,1
3 = Iron Tools	Iron weapons: 0,1

Table 3: Variables in the 1500 A.D. dataset

Variable	Description	Values
<u>Military</u>		
Standing Army	An organization of professional soldiers.	0,1
Cavalry	The use of soldiers mounted on horseback.	0,1
Firearms	Gunpowder based weapons	0,1
Muskets	The successor to the harquebus (the common firearm of European armies) was larger and a muzzle-loading firearm.	0,1
Field Artillery	Large guns that required a team of soldiers to operate. It had a larger caliber and greater range than small arms weapons.	0,1
Warfare capable ships	Ships that were used in battle are considered "warfare" capable.	0,1
Heavy Naval Guns	Ships required significant advances in hull technology before they were capable of carrying heavy guns.	0,1
Ships (+180 guns), +1500 ton deadweight	Large warships that only state navies had the capability of building.	0,1
<u>Agriculture</u>		
Hunting & Gathering	The primary form of subsistence.	0
Pastoralism	The primary form of subsistence.	1
Hand Cultivation	The primary form of subsistence.	2
Plough Cultivation	The primary form of subsistence.	3
<u>Transportation</u>		
Ships Capable of Crossing the Atlantic Ocean	Any ship that had successfully crossed the Atlantic Ocean.	0,1
Ships Capable of Crossing the Pacific Ocean	Any ship that had successfully crossed the Pacific Ocean.	0,1
Ships Capable of Reaching the Indian Ocean	Any ship that had reached the Indian Ocean from either Europe or the Far East.	0,1
Wheel	The use of the wheel for transportation purposes. The most common use was for carts.	0,1
Magnetic Compass	The use of the compass for navigation.	0,1
Horse powered vehicles	The use of horses for transportation.	0,1
<u>Communications</u>		
Movable Block Printing	The use of movable block printing.	0,1
Woodblock or block printing	The use of woodblock printing.	0,1
Books	The use of books.	0,1
Paper	The use of paper.	0,1
<u>Industry</u>		
Steel	The presence of steel in a civilization.	0,1
Iron	The presence of iron in a civilization.	0,1

Table 4: Descriptive statistics of Overall Technology Adoption

<u>Period</u>	<u>Number Obs.</u>	<u>Average</u>	<u>Std. Dev.</u>	<u>Min</u>	<u>Max</u>
1000BC	113	0.45	0.28	0	1
0	135	0.73	0.28	0	1
1500AD	130	0.48	0.32	0	1
Current	109	0.45	0.2	0.15	1

Note: Overall technology adoption measure in a country results from average adoption across technologies in the sector and then averaging sectoral adoption measures across the sectors.

Table 5: Descriptive statistics of Overall Technology Adoption by Continent

<u>Period</u>	<u>Continent</u>	<u>Number Obs.</u>	<u>Average</u>	<u>Std. Dev.</u>	<u>Min</u>	<u>Max</u>
1000BC	Europe	30	0.66	0.16	0.5	1
	Africa	34	0.36	0.31	0	1
	Asia	23	0.58	0.25	0.1	1

0AD	Europe	33	0.88	0.15	0.7	1
	Africa	40	0.77	0.2	0.6	1
	Asia	34	0.88	0.15	0.6	1
	America	25	0.33	0.17	0	0.6
	Oceania	3	0.17	0.11	0.1	0.3
1500AD	Europe	32	0.86	0.07	0.69	1
	Africa	39	0.32	0.2	0.1	0.78
	Asia	25	0.66	0.19	0.07	0.88
	America	24	0.14	0.07	0	0.26
	Oceania	9	0.12	0.04	0	0.13
Current	Europe	34	0.63	0.19	0.27	0.87
	Africa	42	0.31	0.08	0.13	0.54
	Asia	33	0.41	0.15	0.23	0.76
	America	22	0.47	0.17	0.34	1
	Oceania	3	0.73	0.32	0.36	0.92

Table 7: Average Overall Technology Adoption in Advanced Civilizations

<u>Civilization</u>	1000BC	0 AD	1500 AD	Current
W. Europe	0.65	0.96	0.94	0.71
China	0.9	1	0.88	0.33
Indian	0.67	0.9	0.7	0.31
Arab	0.95	1	0.7	0.43

Note: W. Europe includes Spain, Portugal, Italy, France, United Kingdom, Germany, Belgium and Netherlands. Indian Empire includes India, Pakistan and Bangladesh. Arab Empire includes Saudi Arabia, UAE, Yemen, Oman, Iraq, Iran, Syria, Lebanon, Jordan, Egypt, Libya, Tunisia, Algeria and Morocco

Table 7: Cross-country variation in overall technology vs. sectoral technology

<u>Period</u>	<u>N</u>	Std. of deviations from overall tech.					
		<u>Overall</u>	<u>Agriculture</u>	<u>Industry</u>	<u>Military</u>	<u>Transport.</u>	<u>Comm.</u>
1000BC	113	0.28	0.35	0.18	0.16	0.22	0.23
0	136	0.28	0.25	0.24	0.18	0.26	0.32
1500AD	130	0.32	0.2	0.2	0.2	0.12	0.26
Current	152	0.2	0.13	0.12	-	0.11	0.14

Note: Std. Overall is the cross-country standard deviation in overall level of technology adoption.

Std of deviations from overall tech. is the cross-country standard deviation in technology

adoption level in the sector after removing for each country the overall technology adoption level

Table 8: Urbanization rate and technology adoption history

Dependent Variable: Urbanization rate in	1000 B.C.	0 A.D.	1500 A.D.	1000 B.C.	0 A.D.	1500 A.D.
Overall Technology adoption level in 1000BC	2.08 (10.48)			1.96 (15.21)		
Overall Technology adoption level in 0		1.69 (6.99)			1.68 (7.39)	
Overall Technology adoption level in 1500AD			8.04 (2.57)			947 (2.87)
Distance from Equator				0.39 (1.25)	0.16 (0.84)	-3.75 (0.56)
N	113	135	54	106	126	51
R2	0.5	0.58	0.18	0.48	0.59	0.2

Note: t-statistics in parenthesis computed using clustered standard errors.

All regressions include a constant

Table 9: Technology History and Current Development

Dependent Variable	Log Income per capita in 2002						
	I	II	III	IV	V	VI	VII
Overall Technology adoption level in 1000BC	0.75 (1.87)				1.45 (3.19)		
Overall Technology adoption level in 0		0.09 (0.19)				1.49 (1.84)	
Overall Technology adoption level in 1500AD			1.59 (3.22)				3.03 (6.6)
Major European Involvement				1.76 (8.33)	2.47 (8.41)	2.85 (8.18)	3.31 (11.43)
Minor European Involvement				0.1 (0.51)	0.62 (2.17)	0.86 (1.87)	1.51 (4.84)
Constant	8.2 (28.22)	8.45 (19.62)	7.77 (22.1)	8.5 (45.64)	7.68 (22)	7.21 (9.63)	6.74 (27)
N	104	123	110	110	105	123	110
R2	0.03	0	0.18	0.08	0.17	0.13	0.5

Note: t-statistics in parenthesis computed using clustered standard errors.

Major European Involvement is a dummy that is 1 for US, Canada, New Zealand and Australia.

Minor European Involvement is a dummy that is 1 mostly for Latin American, Caribbean Countries and southern Africa.

Table 10: Technology History and Current Technology

Dependent Variable	Current Technology						
	I	II	III	IV	V	VI	VII
Overall Technology adoption level in 1000BC	0.085 (1.37)				0.175 (2.71)		
Overall Technology adoption level in 0		0.014 (0.14)				0.24 (2.14)	
Overall Technology adoption level in 1500AD			0.22 (2.58)				0.45 (6.47)

Table 18: Population technology and development

Dependent Variable:	Current			
	Y/L	Technology	Y/L	Technology
Overall Technology adoption level in 1500AD	3.39 (8.12)	0.5 (6.62)	1.5 (1.98)	0.15 (1.73)
(Log) Population in 2000 AD	-0.25 (2.19)	-0.05 (2.94)	-0.06 (0.52)	-0.015 (0.76)
(Log) Population in 1500 AD	0.06 (0.49)	0.02 (1.09)	0 (0.01)	0.01 (0.61)
Continent Dummies	NO	NO	YES	YES
N	105	109	105	109
R2	0.58	0.57	0.68	0.69

Note: t-statistics in parenthesis computed using clustered standard errors.
 All regressions include a constant and European influence dummies

Table 19: Persistence of Technology within sectors

Dependent Variable:	Technology _{cst}							
	I	II	III	IV	V	VI	VII	VIII
Technology _{cst-1}	0.95 (7.66)	0.85 (7.39)	0.31 (4.67)	0.41 (5.47)	0.17 (2.55)	0.27 (3.07)	0.46 (4.54)	0.34 (4.64)
Country-Sector Fixed effects	YES	YES	YES	YES	YES	YES	YES	YES
Country time-varying effects	YES	NO	YES	NO	YES	YES	YES	YES
Technology-specific trends	NO	NO	YES	YES	YES	YES	YES	YES
Sectors excluded other than military	-	-	-	-	Agri.	Comm.	Transp.	Indust.
N	405	405	405	405	303	300	305	307
R2	-	-	0.4	0.35	0.38	0.45	0.18	0.53

Note: Panel regression using technology adoption level in sector, s , in country, c , in year t . t includes years 2000 AD and 1500 AD.

Most general regression is: $\text{Technology}_{cst} = \alpha_{cs} + \alpha_{ct} + \alpha_s * t + \beta * \text{Technology}_{cst-1} + \epsilon_{cst}$

where α_{cs} is a country-sector fixed effect, α_{ct} is a country time-varying effect, α_s is a technology specific trend and ϵ_{cst} is the error term.

Regressions are estimated taking time differences as follows: $\text{Technology}_{cst} - \text{Technology}_{cst-1} = \alpha_{ct} - \alpha_{ct-1} + \alpha_s + \beta * (\text{Technology}_{cst-1} - \text{Technology}_{cst-2}) + \epsilon_{cst} - \epsilon_{cst-1}$

To avoid biases due to lagged dependent variable, $(\text{Technology}_{cst-1} - \text{Technology}_{cst-2})$ is instrumented with $\text{Technology}_{cst-2}$

t-statistics in parenthesis computed using clustered standard errors. All regressions include European influence dummies when $t=2000$.

Table A.1: Primitive technology and current development, robustness checks

Dependent Variable: Log Income per capita in	1913			1960			1990		
	I	II	III	IV	V	VI	IV	V	VI
Overall Technology adoption level in 1000BC	-0.36 (0.62)			0.78 (2.32)			1.14 (2.28)		
Overall Technology adoption level in 0		1.08 (1.62)			1.27 (2.6)			1.35 (1.81)	
Overall Technology adoption level in 1500AD			2.14 (4.91)			1.87 (4.85)			2.98 (6.47)
N	51	60	57	95	116	103	107	129	113
R2	0.18	0.28	0.4	0.17	0.18	0.4	0.14	0.12	0.5

Note: t-statistics in parenthesis computed using clustered standard errors. Major and minor European influence dummies included in all regressions.

Table A2: Average adoption level by sector in the Empires

Year	Empire	Sectors				
		Agriculture	Industry	Communications	Transportation	Military
1000 B.C.	W. Europe	1	1	0.125	0.5625	0.56
	China	1	1	1	1	0.5
	Indian	1	0.83	0.33	0.5	0.66
	Arab	1	1	1	1	0.75
0 A.C.	W. Europe	1	1	0.875	0.9375	1
	China	1	1	1	1	1
	Indian	1	1	0.66	0.83	1
	Arab	1	1	1	1	1
1500 A.D.	W. Europe	1	1	1	0.6875	0.968
	China	1	1	1	0.66	0.75
	Indian	1	1	0.5	0.55	0.458
	Arab	0.85	0.94	0.527	0.57	0.61

Note: W. Europe includes Spain, Portugal, Italy, France, United Kingdom, Germany, Belgium and Netherlands. Indian Empire includes India, Pakistan and Bangladesh. Arab Empire includes Saudi Arabia, UAE, Yemen, Oman, Iraq, Iran, Syria, Lebanon, Jordan, Egypt, Libya, Tunisia, Algeria and Morocco
